

The two blocks are different kinds of thing: *epsA*-*slrR* is one clade of 47 clones sharing an ancestral variant, while the *sinR* block is five independent mutations that share only the absence of it, shown here one shade per allele. Private mutations per clone are 0.28, 0.20 and 0.41 in the *epsA*-*slrR*, *sinR* and remaining clones (Poisson GLM $P = 0.49$), so neither clade mutates faster.
