
The two blocks are different kinds of thing: epsA−slrR is one clade of 47 clones sharing an ancestral variant, while the sinR block is five independent mutations that share only the absence of it, shown here one shade per allele. Private mutations per clone are 0.28, 0.20 and 0.53 in the epsA−slrR, sinR and remaining clones (Poisson GLM P = 0.20), so neither clade mutates faster.
